Logging for Crash Recovery

ACID: Atomicity and Durability

Review: The ACID properties

- Atomicity: All actions in the transaction happen, or none happen.
- Consistency: If each transaction is consistent, and the DB starts consistent, it ends up consistent.
- Isolation: Execution of one transaction is isolated from that of other transactions.
- Durability: If a transaction commits, its effects persist.
- Question: which ones does the Recovery Manager help with?

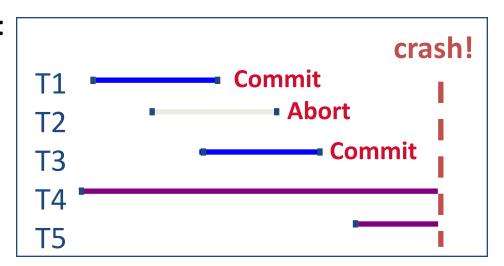

Atomicity & Durability (and also used for Consistency-related rollbacks)

Motivation

- Atomicity:
 - Transactions may abort ("Rollback").
- Durability:
 - What if DBMS stops running? (Causes?)

Desired state after system restarts:

- T1 & T3 should be durable.
- T2, T4 & T5 should be aborted (effects should not be seen).

Assumptions

- Concurrency control is in effect.
 - Strict 2PL, in particular.
- Updates are happening "in place".
 - i.e. data is overwritten on (deleted from) the actual page copies (not private copies).

Buffer Management Plays a Key Role

- Force policy make sure that every update is on disk before commit.
 - Provides durability without REDO logging.
 - But, can cause poor performance.
- No Steal policy don't allow buffer-pool frames with uncommited updates to overwrite committed data on disk.
 - Useful for ensuring atomicity without UNDO logging.
 - But can cause poor performance.

Of course, there are some nasty details for getting Force/NoSteal to work...

Preferred Policy: Steal/No-Force

- This combination is most complicated but allows for highest performance.
- NO FORCE (complicates enforcing Durability)
 - What if system crashes before a modified page written by a committed transaction makes it to disk?
 - Write as little as possible, in a convenient place, at commit time, to support REDOing modifications.
- STEAL (complicates enforcing Atomicity)
 - What if the transaction that performed updates aborts?
 - What if system crashes before transaction is finished?
 - Must remember the old value of P (to support UNDOing the write to page P).

Buffer Management summary

	No Steal	Steal		No Steal	Steal
No Force		Fastest	No Force	No UNDO REDO	UNDO REDO
Force	Slowest		Force	No UNDO No REDO	UNDO No REDO

Performance Implications Logging/Recovery Implications

Basic Idea: Logging

- Record REDO and UNDO information, for every update, in a log.
 - Sequential writes to log (put it on a separate disk).
 - Minimal info (diff) written to log, so multiple updates fit in a single log page.
- Log: An ordered list of REDO/UNDO actions
 - Log record contains:
 - <XID, pageID, offset, length, old data, new data>
 - and additional control info (which we'll see soon).

Write-Ahead Logging (WAL)

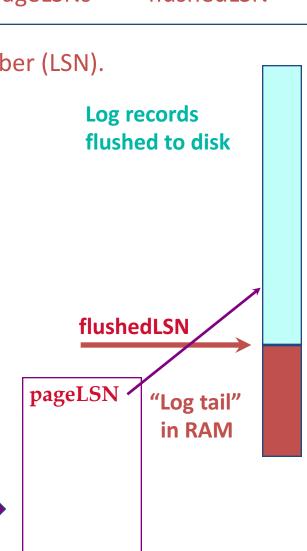

- The Write-Ahead Logging Protocol:
 - 1. Must force the log record for an update <u>before</u> the corresponding data page gets to disk.
 - 2. Must force all log records for a Xact <u>before commit</u>. (e.g. transaction is not committed until all of its log records including its "commit" record are on the stable log.)
- #1 (with UNDO info) helps guarantee Atomicity.
- #2 (with REDO info) helps guarantee Durability.
- This allows us to implement Steal/No-Force
- Exactly how is logging (and recovery!) done?
 - We'll look at the ARIES algorithm from IBM.

WAL & the Log

- Each log record has an unique Log Sequence Number (LSN).
 - LSNs are always increasing.
- Each <u>data page</u> contains a pageLSN.
 - The LSN of the most recent log record for an update to that page.
- System keeps track of flushedLSN.
 - The max LSN flushed so far.
- WAL: For a page i to be written must flush log at least to the point where:

pageLSN_i ≤ flushedLSN

Log Records

LogRecord fields: LSN prevLSN XID type pageID length update offset records before-image only after-image

log record written by this
transaction (so records of an
transaction form a linked list
backwards in time)

Possible log record types:

- Update, Commit, Abort
- Checkpoint (for log maintenance)
- Compensation Log Records (CLRs)
 - for UNDO actions
- End (end of commit or abort)

Other Log-Related State

- In-memory table:
- Transaction Table
 - One entry per <u>currently active transactions</u>.
 - entry removed when the transaction commits or aborts
 - Contains XID, status (running/committing/aborting), and lastLSN (most recent LSN written by transaction).

Also: Dirty Page Table (will cover later ...)

The Big Picture: What's Stored Where

LogRecords

Dirty Page Table recLSN

flushedLSN

Normal Execution of a transaction

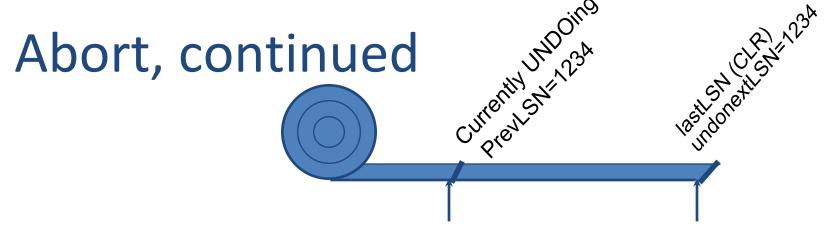

- Series of reads & writes, followed by commit or abort.
 - We will assume that disk write is atomic.
 - In practice, additional details to deal with non-atomic writes.
- Strict 2PL.
- STEAL, NO-FORCE buffer management, with Write-Ahead Logging.

Transaction Commit

- Write commit record to log.
- All log records up to transaction's commit record are flushed to disk.
 - Guarantees that flushedLSN ≥ lastLSN.
 - Note that log flushes are sequential, synchronous writes to disk.
 - Many log records per log page.
- Commit() returns.
- Write end record to log.

Simple Transaction Abort

- For now, consider an explicit abort of a Xact.
 - No crash involved.
- We want to "play back" the log in reverse order, UNDOing updates.
 - Get lastLSN of Xact from Xact table.
 - Can follow chain of log records backward via the prevLSN field.
 - Write a "CLR" (compensation log record) for each undone operation.
 - Write an *Abort* log record before starting to rollback operations.

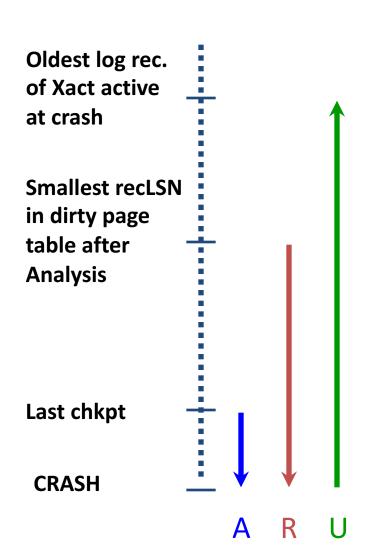

- To perform UNDO, must have a lock on data!
 - No problem (we're doing Strict 2PL)!
- Before restoring old value of a page, write a CLR:
 - You continue logging while you UNDO!!
 - CLR has one extra field: undonextLSN
 - Points to the next LSN to undo (i.e. the prevLSN of the record we're currently undoing).
 - CLRs never Undone (but they might be Redone when repeating history: guarantees Atomicity!)
- At end of UNDO, write an "end" log record.

Checkpointing

- Conceptually, keep log around for all time. Obviously this has performance/implementation problems...
- Periodically, the DBMS creates a <u>checkpoint</u>, in order to minimize the time taken to recover in the event of a system crash. Write to log:
 - begin_checkpoint record: Indicates when chkpt began.
 - end_checkpoint record: Contains current transaction table and dirty page table. This is a 'fuzzy checkpoint':
 - Other Xacts continue to run; so these tables accurate only as of the time of the begin_checkpoint record.
 - No attempt to force dirty pages to disk; effectiveness of checkpoint limited by oldest unwritten change to a dirty page.
 - Store LSN of most recent checkpoint record in a safe place (master record).

Crash Recovery: Big Picture

- Start from a checkpoint (found via master record).
- Three phases. Need to do:
 - Analysis Figure out which transactions committed since checkpoint, which failed.
 - REDO all actions.
 (repeat history)
 - UNDO effects of failed transactions.

Recovery: The Analysis Phase

- Re-establish knowledge of state at checkpoint.
 - via transaction table and dirty page table stored in the checkpoint
- Scan log forward from checkpoint.
 - End record: Remove Xact from Xact table.
 - All Other records: Add Xact to Xact table, set lastLSN=LSN, change Xact status on commit.
 - also, for Update records: If page P not in Dirty Page Table,
 Add P to DPT, set its recLSN=LSN.

At end of Analysis...

- transaction table says which xacts were active at time of crash.
- DPT says which dirty pages <u>might not</u> have made it to disk

Phase 2: The REDO Phase

- We Repeat History to reconstruct state at crash:
 - Reapply all updates (even of aborted transactions!), redo
 CLRs.
- Scan forward from log rec containing smallest recLSN in DPT.
 Q: why start here?
- For each update log record or CLR with a given LSN, REDO the action unless:
 - Affected page is not in the Dirty Page Table, or
 - Affected page is in D.P.T., but has recLSN > LSN, or
 - pageLSN (in DB) ≥ LSN. (this last case requires I/O)
- To REDO an action:
 - Reapply logged action.
 - Set pageLSN to LSN. No additional logging, no forcing!

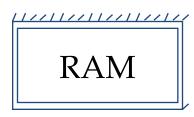

Phase 3: The UNDO Phase

ToUndo={lastLSNs of all Xacts in the Xact Table} Repeat:

- Choose (and remove) largest LSN among ToUndo.
- If this LSN is a CLR and undonextLSN==NULL
 - Write an End record for this transation.
- If this LSN is a CLR, and undonextLSN != NULL
 - Add undonextLSN to ToUndo
- Else this LSN is an update. Undo the update, write a CLR, add prevLSN to ToUndo.

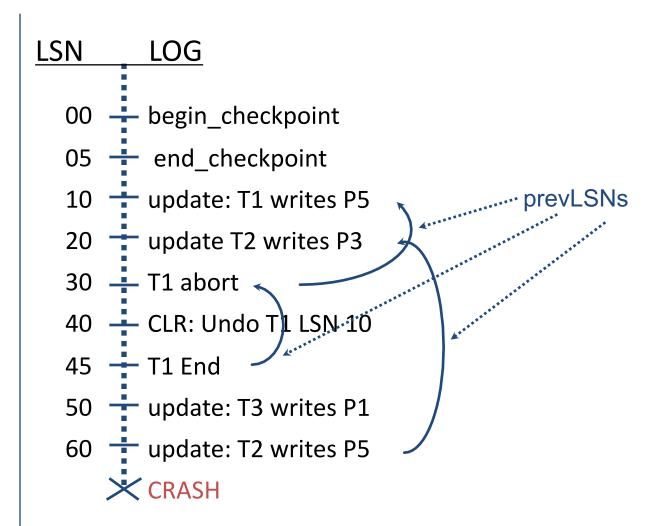

Until ToUndo is empty.

Example of Recovery

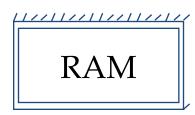

Xact Table
lastLSN
status
Dirty Page Table
recLSN
flushedLSN

ToUndo

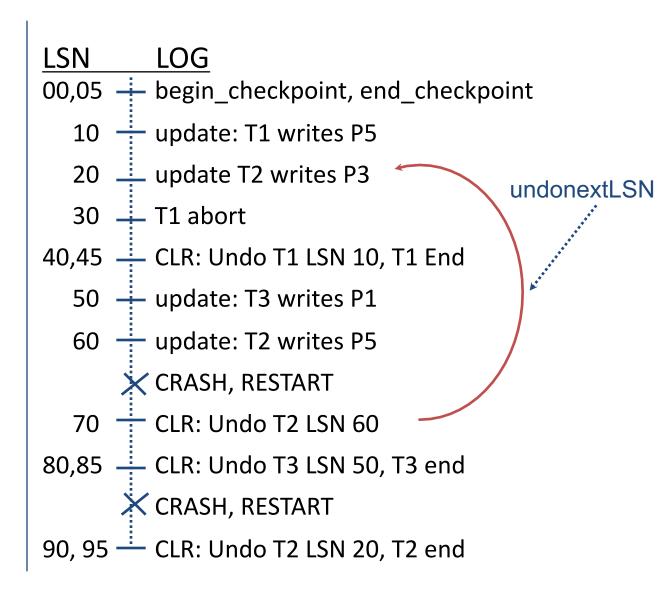

Example: Crash During Restart!

Xact Table
lastLSN
status
Dirty Page Table
recLSN
flushedLSN

ToUndo

Additional Crash Issues

 What happens if system crashes during Analysis? During REDO?

- How do you limit the amount of work in REDO?
 - Flush asynchronously in the background.

- How do you limit the amount of work in UNDO?
 - Avoid long-running transactions.

Summary of Logging/Recovery

- Recovery Manager guarantees Atomicity & Durability.
- Use WAL to allow STEAL/NO-FORCE without sacrificing correctness.
- LSNs identify log records; linked into backwards chains per transaction (via prevLSN).
- pageLSN allows comparison of data page and log records.

Summary, continued

- Checkpointing: A quick way to limit the amount of log to scan on recovery.
- Recovery works in 3 phases:
 - Analysis: Forward from checkpoint.
 - Redo: Forward from oldest recLSN.
 - Undo: Backward from end to first LSN of oldest Xact alive at crash.
- Upon Undo, write CLRs.
- Redo "repeats history": Simplifies the logic!
